COMPREHENSIVE ACTUARIAL REVIEW OF THE
2017 ACTUARIAL VALUATION OF THE
LOUISIANA ASSESSORS’ RETIREMENT FUND

ACTUARIAL SERVICES
PRESENTED TO THE PUBLIC RETIREMENT SYSTEMS’ ACTUARIAL COMMITTEE
SEPTEMBER 6, 2018
August 27, 2018

Ms. Kathy Bertrand, Interim Executive Director
Louisiana Assessors’ Retirement Fund
3060 Valley Creek Drive
Baton Rouge, LA 70808

Re: Comprehensive Actuarial Review of the 2017 Actuarial Valuation

Dear Ms. Bertrand:

To fulfill the requirements of R.S. 11:127(C), the Louisiana Legislative Auditor (LLA) prepares a Comprehensive Actuarial Review (CAR) every other year for each of the statewide retirement systems. Your system, the Assessors’ Retirement Fund (LARF), receives a comprehensive review for funding valuations associated with odd-numbered years. The remainder of this letter contains the results of our comprehensive review of your September 30, 2017 Actuarial Valuation (prepared by G.S. Curran & Company (GSC) and dated January 18, 2018). More specifically, we have evaluated for reasonableness the actuarial assumptions and methods employed by the System and its actuary.

Based on our review, we expect to recommend that the Public Retirement Systems’ Actuarial Committee (PRSAC) not accept LARF’s funding valuation. While we commend the LARF board for lowering the return assumption from 7.00% to 6.75%, we consider it to be too optimistic in light of the preponderance of expert opinions suggesting that a significantly lower return assumption is more appropriate. We found a consensus average of major national forecasting firms for the LARF’s own portfolio coupled with its own liability duration to be approximately 5.50%. The 6.75% assumption is out of the mainstream, even considering a range (plus or minus 75 basis points) around the consensus forecast.

Therefore, we expect to recommend this valuation report not be accepted but revised to use a return assumption of no more than 6.25% with a formal commitment and adoption of a plan to lower it again in following year(s) as consensus evidence indicates.

I would like to thank you and your staff for your cooperation and assistance with this review. Your formal response to this review has been incorporated into Appendix B of this letter.

Sincerely,

Daryl G. Purpera, CPA, CFE
Legislative Auditor

DGP:PTR:ch

CC: G.S. CURRAN & COMPANY

2017 COMPREHENSIVE ACTUARIAL REVIEW FOR LARF
Scope of Review

The September 30, 2017 Actuarial Valuation Report for LARF for funding purposes (2017 Funding Valuation) was prepared by the actuary for LARF’s retirement board, GSC, and dated January 18, 2018.

This Comprehensive Actuarial Review (CAR) was prepared by the actuary for the LLA, Mr. Paul Richmond, and includes evaluations and recommendations concerning key actuarial assumptions and methods for appropriateness. This CAR presents documented evidence for the opinions expressed herein concerning various assumptions and methods employed by the board and its actuary in the 2017 Funding Valuation.

Summary of Findings

A summary of our findings follows. Additional details are addressed in the remainder of this report.

1. **Overly Optimistic Return Assumption.** The net inflation assumption, which is one of the building blocks included within the net investment return assumption, is at the highest end of our range, being higher than all but one of our sources of inflation forecasting. The board’s 6.75% net investment return assumption for 2017 is also outside the consensus mainstream of professional investment forecasters. It is, in our opinion, overly optimistic compared to a preponderance of expert investment forecasters. A more appropriate net return assumption would be 5.50% per year. Even though the board and actuary lowered the return assumption from 7.0% in 2016, the 6.75% assumption is still overly optimistic for use in the 2017 Funding Valuation. All valuation assumptions need to stand on their own each year.

   Refer to “Section 1: Overly Optimistic Return Assumption” of this report for details.

2. **Mortality Assumption.** Careful analysis was undertaken by the board’s actuary, in accordance with methods outlined in current actuarial literature, specifically for assessing the degree of plan-specific mortality experience that should be recognized in the mortality tables assumed for the 2017 Funding Valuation. The current mortality assumption is acceptable.

   Refer to “Section 2: Mortality Assumption” of this report for details.

3. **Withdrawal Assumption.** The rates of withdrawal are slightly different than disclosed in the experience study. However, we do not believe the discrepancy is a material issue, and we have not attempted to determine the impact it would have on the actuarial accrued liability.

   Refer to “Section 3: Withdrawal Assumption” of this report for details.

4. **Gain-sharing Cost-of-Living Adjustments (COLAs).** The cost of future COLAs is currently not included in the 2017 Funding Valuation. We recommend that the board (a) engage its actuary to model the likelihood and dollar amounts of future cost-of-living increases funded with “excess” investment earnings, as permitted by the statutory template and (b) incorporate permitted future cost-of-living increases in the measurement of the plan’s costs and liabilities to the extent they are considered material for actuarial and accounting purposes.

   Refer to “Section 4: Cost-of-living Adjustments” of this report for details.
As a result of the findings summarized above, with particular regard for the overly optimistic return assumptions, I cannot endorse the September 30, 2017 actuarial valuation prepared for LARF. I realize that other actuaries may have different opinions on the future than I have. However, I trust you will give consideration to the robust methodology and process by which I arrived at my opinion.

I have relied on research provided by Gabriel, Roeder, Smith & Company (GRS); however, I am solely responsible for my opinions. GRS bears no responsibility for the opinions I have expressed in this report. I reviewed their work carefully, as I do for any other external resource, in forming my opinions and in drafting and signing this Comprehensive Actuarial Review. Please refer to my certification at the end of this report.
Section 1: Overly Optimistic Return Assumption

In our opinion, the assumed rate of return used by LARF and its actuary (6.75% as of September 30, 2017) is overly optimistic compared to a consensus of independent expert investment consultants and forecasters. Our rationale for this conclusion follows.

This section sets forth (a) our evaluation of LARF’s defense of 6.75% as a return assumption and (b) a disciplined process for setting a return assumption that ensures it is mainstream and defensible, and provides the details for how we arrived at 5.50% as the more appropriate net return assumption.

LARF’s Support of its 6.75% Assumption

The LLA sent an entry data request letter to LARF’s executive director on March 8, 2018. Among other items, it requested information on the investment return assumption intended to be used in actuarial calculations.

LARF’s actuary responded on March 15, 2018 to the LLA’s entry data request letter with the following:

- On page 5, “Based upon our review of inflation related data, the current 2.5% inflation assumption is within the reasonable range for such a long-term assumption. This assumption will be further reviewed within the next experience study along with the valuation interest rate and the assumed rate of salary increase. The reduction to the valuation interest rate for LARF from 7.00% to 6.75% was based on the Board’s desire to reduce risk within its funding structure and a recognition that, based on the plan’s asset portfolio size, the system may not have as many investment options within each of the asset classes as a larger retirement system. Therefore, this represents a reduction to the expected real rates of return on invested assets.”

While it is commendable to lower the assumed rate of net return, the action taken by the LARF board is, in our opinion, too little. Setting the net return assumption for the 2017 Funding Valuation report at 6.75% makes it an outlier compared to a consensus of our independent investment forecasters. The 2017 Funding Valuation stands on its own.

A Disciplined Process

The cost of being wrong is substantial, especially if it is over a 10-year or 30-year period, and could be detrimental to both plan members and taxpayers. To take this evaluation of LARF’s net return assumption a step further, consider the subsection below which describes a process for setting or evaluating a net return assumption that:

a. Is unbiased, objective, and free of agency risk;

b. Is disciplined and robust;

c. Is defensible; and

d. Improves intergenerational equity, contribution stability, and benefit security of plan members.
The most significant factors in setting or evaluating an assumed return are:

a. The horizon over which returns are expected to be satisfied;

b. Future rates of inflation (forward-looking), as expected by a consensus of experts in the field of inflation forecasting who are both independent and nationally recognized;

c. Current and future asset allocation percentages by asset class; and

d. Future investment performance (forward-looking) and other capital market assumptions for various asset classes, as expected by a consensus of experts in the field of investment forecasting who are both independent and nationally recognized.

**Horizons**

There is an ongoing debate over the time horizon that should be used to set the rate of return assumption. Some have posited that pension plans are long-term propositions and their return assumptions should reflect a long-term horizon, for example, 30 years. Others believe that a shorter time horizon should be used. It is our opinion that a forward-looking mid-term horizon should influence the final choices of return assumptions. Investment forecasters generally issue 10-year horizon forecasts while some issue 20- or 30-year horizon forecasts. So the closest to a mid-term horizon would be to use the available 10-year horizon forecasts.

Furthermore, this system’s “duration” is approximately 9.6 years. “Duration” is the present value weighted average length of time till the benefits are paid. This points to the usefulness of the 10-year forecasts as representative of a mid-term outlook. Long-term horizon forecasts (e.g., 20-30 years) are useful for discussion purposes, but not to the exclusion of mid-term horizons. Pension funds are, indeed, usually long-term arrangements. However, in our opinion (for the reasons cited below), 30 years is too long for the selection of a pension fund’s expected rate of return.

Some of the reasons supporting the use of a mid-term horizon are:

a. Underperformance in the mid-term may not be sustainable. If the forecasting experts are correct, there will be lower compounded returns over the next decade or two while waiting for the following decades to bail out pension plans in order to achieve the higher long-term expectation. Undoubtedly, there will be better-than-assumed years on occasion. But a consensus of independent experts says (in the support outlined below, in various investment periodicals and in retirement conferences across the country) the next decade is expected to see compound returns well below LARF’s current 6.75% assumed rate.

Anticipating higher returns in the long-term, while regularly suffering underperformance in the mid-term, is not sustainable. It causes repeated contribution rate increases and a lack of progress in paying down the unfunded actuarial liability. It will test the patience and tolerance of taxpayers, elected representatives, and budget directors, and may push them into serious consideration of proposed retirement plan designs that transfer all or some of the investment risk onto plan members.

b. Forecasts for 30-year long-term horizons are the least reliable. There is less certainty in long-term forecasts than mid-term forecasts. In the face of uncertainty, investors become more conservative. Thus, decision-makers should consider being more conservative than the longest-term forecasts indicate because the longest-term forecasts are more uncertain. This is a truism,
whether in financial forecasting, election forecasting, or hurricane forecasting. Long-term forecasts are less reliable than mid-term forecasts.

No one knows the future for certain. When in doubt, in our opinion it is best to err on the side of conservatism (lower return assumptions).

c. **Duration of the liability.** The duration of LARF’s plan liabilities is approximately 9.6 years. Relying too much on a 30-year horizon for return expectations fails to recognize the near-term and mid-term cash demands upon the plan. A large portion of this system’s expected benefits will be paid out of the fund in the next 10-15 years, and will not be in the fund to enjoy the higher returns expected in the longer term. This is a purely mathematical and actuarial reason why it is more appropriate to rely on mid-term horizon forecasts, rather than 30-year forecasts.

The use of a single equivalent rate, calculated and adjusted by the system’s own expected benefit stream (similar to duration), would likely result in an assumed rate between the 10-year forecast consensus and the 30-year forecast consensus. That is a step that recognizes the system’s own cash flow, rather than blindly applying either the 10-year horizon forecast or the 30-year horizon forecast without regard to the system’s own demographics.

**Perspectives**

There are two types of perspectives to consider when defending or determining assumptions for a future net rate of return of a pension fund and a future rate of inflation. One is temporal – Do we look more to historical rates to inform decision-makers or more to forward-looking forecasts of the future? The other is social – Do we look more to what other retirement systems are doing or look more to what expert forecasters would expect for LARF’s own portfolio in the future?

**Temporal.** Historical rates of return and inflation are viewed more as mere information, than used to defend or determine a current net return or inflation assumption. The past is indeed useful for understanding historical relationships among various economic forces and various statistical metrics such as standard deviations, correlation coefficients and P/E ratios; but even those have been known to change over time and may be different from their historical averages. Certainly, past performance should not be a driver in decision-making.

The current domestic and global environments are not like the past 10, 30, or 50 years; and the future domestic and global environments are certain to be different from the past. A forward-looking perspective should drive the defense or determination of a net return assumption for pension actuarial valuations. Strategically selecting historical returns (an X-year period ending on Y-date) to justify a net return assumption being applied to the next 10-, 20-, or 30-year period is not valid.

Past performance is not an indicator of future performance.

**Social.** Looking to what other peer retirement systems have adopted for their own net return assumptions should not be a driver in decision-making. Other retirement systems have their own asset allocation and expense structure and their own set of politics, protectionism, budget issues, and agency risk. They are not the best source to turn for defense or determination of another system’s net return assumption.

Independent, unbiased, expert sources of inflation and investment return forecasts are the best places to look for input when setting a net return assumption for pension valuations. These are much more objective and unfiltered sources – obtained directly from the experts themselves, to guide decision-makers.
Adopting a process that looks to a consensus of external subject matter experts’ forward-looking forecasts is the best way to avoid political and budget pressures that sometimes distract or influence assumption-setters away from their primary duty to set return assumptions as their unbiased best estimate of future.

**Inflation**

An assumed rate of future inflation is a component of the assumed return assumption and the salary increase assumptions. When inflation rates are lowered, the return and salary increases should be lowered (unless there is a coincidental change in real returns or real salary increases that offset it). Conversely, when inflation rates are increased, the return and salary increases should be increased. Expected future inflation is a critical component of the other assumptions. Therefore, much care and attention should be given to the expected future rates of inflation.

LARF’s 2017 Funding Valuation (page 4) states: “An inflation of 2.5% was implicit in both the assumed rate of return and the rate of salary increases.”

We suggest an inflation assumption closer to the 2.25% supported by the research on expected inflation rates in Exhibits 2 and 3. However, we do not find the use of 2.50% in the LARF funding valuation to be unreasonable for the purpose at hand.

Currently, expert professional sources for forward-looking inflation forecasts generally lie between 1.73% and 2.60%. Consider the forward-looking forecasts from the following subject matter experts.

**Exhibit 1**

</tbody>
</table>
It has become increasingly difficult to support inflation assumptions greater or equal to 2.50% in the face of so many opinions to the contrary from experts in the field of inflation forecasting.

Our preferred inflation assumption would currently be 2.25% because it lies more comfortably near a consensus of the expectations in the summary table above and the detailed table below. A 2.50% inflation expectation lies at the very upper end of the range of professional forecasters presented above.

Consider Exhibit 3, which shows inflation forecasts of these eight large reputable experts in the field of inflation forecasting.

Asset Allocation

It has been generally accepted for many years that a fund’s asset allocation is responsible for the vast majority of a fund’s investment performance. Therefore, the asset allocation of the System is a core element in setting and evaluating assumed future returns.

In our evaluation of the actuary’s net return assumption, we first relied on the 7 target asset allocation percentages set forth in System’s formal Investment Policy Statement (IPS) last updated January 2018. We then relied on page 25 of a document from the System (“M_2018_03_14_15_55_42_094”), prepared by the investment consultant (AndCo), to further separate these percentages into 12 target asset allocation percentages.

Exhibit 4

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>Total Risk Assets 70.0%</strong></td>
</tr>
<tr>
<td><strong>Total Asset Allocation 100.0%</strong></td>
</tr>
</tbody>
</table>

It should be noted that LARF’s asset allocation is more conservative than other state and statewide systems. Consequently, it is expected that the forecasted net returns would be lower than for the other state and statewide systems.

Consensus of Professional Investment Forecasts

We applied the target asset allocations to the expectations in the GRS Survey of 10 major national investment consultants and forecasters. Eight of these 10 investment consultants/forecasters provided GRS with their mid-term (10 years) horizon forecasts, and four of them provided GRS with their longer-term (20- to 30-year) horizon forecasts. Given the brevity of the descriptions of the asset classes identified, our mapping of these 12 asset classes to the investment consultant’s asset classes may not be exact.
Listed below are the national firms in our 2017 GRS Survey. These are very large and reputable investment consultants and forecasters.

*Each firm has between $1 trillion and $10 trillion in worldwide assets under management or advisement; the others are large managers and advisors below $1 trillion.*

We applied the investment forecasters’ expected returns to LARF’s asset allocation. We replaced the investment forecasters’ respective inflation assumptions with 2.25%, our preferred assumption based on the consensus of expert inflation forecasters’ expectations presented above in order to normalize for a consistent inflation assumption across all forecasters.

We reduced the respective forecasts for LARF by the expected investment-related expenses and added alpha back in to replace active management expenses above expected passive management expenses, as permitted and limited by Actuarial Standard of Practice No. 27. This leaves a net reduction estimated to be for passive investments.

This process results in normalized expected returns for any one given year in the forecast horizon (called the expected arithmetic return). Finally, we reduced the resultant one-year arithmetic returns for volatility drag in the compound return expected over time, because pensions are all about compounding in a volatile environment over the horizon.

It matters not whether the field of forecasting is for hurricanes, earthquakes, elections, or inflation and investment returns, a consensus average of many reputable experts is proven to be more accurate than any one of those experts.
Below are the results of this process for the mid-term horizon.

<td>4.61%</td>
<td><strong>5.54%</strong></td>
</tr>
</tbody>
</table>

There are three important takeaways from Exhibit 6:

a. Over the mid-term horizon the range of expectations of the 50th percentile of compound average return runs from 4.76% to 6.33%.

b. The 50th percentile consensus average mid-term forecast is 5.54%, or rounded to 5.50%.

c. The consensus of these experts is that there is only a 37.30% chance of achieving at least the current 6.75% over the mid-term horizon. This does not mean a 37.30% chance of achieving the 6.75% assumption in any year during the horizon; it means that the compound return over the next 10 years has a 37.30% chance of achieving at least the 6.75% assumption.

This is why, actuarially speaking, the 5.54% rate of return is the preferred assumption for funding because it is the 50th percentile expectation of compound returns over a mid-term horizon. The consensus is that there is a 50-50 chance of returning at least 5.54% when compounded over the next 10 years.

None of the eight major national investment consultants with mid-term horizon forecasts expect the 50th percentile of the compound return to be at or above the current 6.75% assumption over the next 10 years. There are good reasons for these professionals’ bleak mid-term forecasts, the details of which are beyond the scope of this report.
If the independent experts are right, the next 10-year period will experience a substantial shortfall, while the board hopes to be bailed out in years 11 through 30.

Below are the results of this process for the long-term horizon.

**Exhibit 7**

**Expected Likelihood of Achieving Forecast Results**
**Based on a 25-year Time Horizon**

<table>

<td><strong>Average</strong></td>
<td><strong>5.58%</strong>  <strong>6.18%</strong>  <strong>6.79%</strong>  <strong>40.62%</strong></td>
<td></td>
</tr>
</tbody>
</table>

There are three important takeaways from Exhibit 7:

a. Over the long-term horizon the range of expectations of the 50th percentile of compound average return runs from 6.01% to 6.34%.

b. The 50th percentile expectation of the consensus average for the long-term horizon is 6.18%, or rounded to 6.25%.

c. The consensus of these experts is that there is only a 40.62% chance of achieving at least the current 6.75% over the long-term horizon. This does not mean a 40.62% chance of achieving the 6.75% assumption in any year during the horizon; it means that the compound return over the next 25 years has a 40.62% chance of achieving at least the 6.75% assumption.

None of the four consultants with longer term forecasts expects a 50-50 chance of achieving the 6.75% return over 25 years.

This makes the current 6.75% assumption an outlier among the mainstream investment forecasters. According to the capital market assumptions of these investment forecasters, there is only a 37.30% chance of achieving at least the 6.75% compound annual return over the next 10-year period and only a 40.62% chance over the next 25-year period.

For use in an actuarial valuation for pensions, where the entire measurement and funding model is built on compounding (present values and future values), the 50th percentile compound or geometric expectation over a mid-term horizon are the most appropriate choices of a net return assumption.
Again, no one knows the future for certain. When in doubt, in our opinion it is best to err on the side of conservatism (lower return assumptions), relying on the experts to form those opinions.
Section 2: Mortality Assumption

The 2017 Actuarial Valuation (page 40) states that the mortality assumption for annuitant and beneficiary mortality is the “RP 2000 Healthy Annuitant Table set forward 1 year and projected to 2030 for males and projected to 2030 for females with no set forward.”

Base table

To evaluate the reasonableness of the mortality assumption, we reviewed the base mortality (RP2000) separately from the projection scale (Scale AA).

We believe the use of the RP2000 as the base mortality table to be reasonable. The process we used to determine the reasonableness of the base mortality table is as follows:

1. Experience Study: An experience study (dated January 25, 2016) was prepared covering the period from July 1, 2009, through September 30, 2014. We reviewed the experience study report and found the section on mortality to be described with reasonable detail and careful recognition of relevant mortality experience. The report describes reasonable applications of actuarial credibility principles.

2. Size of the plan: Due to the small size of the experience group and low number of deaths during the study period, the results of the experience study are not fully credible. Only partial credibility can therefore be given to the results of the experience study. A weighted average of the group’s experience and that of a standard reference table is needed to obtain a final mortality assumption for valuation purposes.

3. Standard mortality table: Since the experience study is not fully credible, it is necessary to select a standard mortality table as a reference table to be used in the determination of the mortality assumption. Possible candidates for a standard reference table include:

   a. The mortality tables developed for LASERS or TRSL. However, an actuarial assessment would need to be made of the appropriateness of the actuarial methodology and the comparability of the groups covered before considering them for use as the standard reference table for this purpose.

   b. The RP2000 mortality table was published in or around the year 2000. It was developed by the Society of Actuaries based on national private sector pension data.

   c. RP2014 mortality table was published in October 2014. As for RP2000, this table was also developed by the Society of Actuaries based on national private sector pension data. It is the most recent reliable base mortality table available, for purposes of national estimates of mortality for pension plans.

4. Louisiana mortality rates: The Centers for Disease Control and Prevention (CDC) has published data\(^1\) demonstrating that mortality rates in Louisiana are generally higher than national averages. Therefore, it would be more prudent not to use a current national mortality table (such as

---

\(^1\) Refer to Table 3 in the *National Vital Statistics Reports* (Volume 60, Number 4) dated January 22, 2012, published by the U.S. Department of Health and Human Services, Centers for Disease Control and Prevention, National Center for Health Statistics, National Vital Statistics System.
RP2014) as the standard reference table in the weighted average calculations described above without adjustment.

5. **RP2000 as the standard mortality table:** The experience study states that RP2000 mortality table was selected as the standard base mortality table. The RP2014 mortality table, being the newest table available, was considered by the system’s actuary. However, the RP2000 mortality table was ultimately selected to account for the higher mortality rates in Louisiana. We find this approach reasonable. We analyzed the data from CDC and found that mortality rates in Louisiana are approximately 20% higher than national mortality rates. We found the mortality rates in RP2000 to be approximately 26% higher than those of RP2014 (representative of national rates). In our opinion, this is close enough for RP2000 to qualify as a reasonable standard reference table for reflecting general Louisiana mortality.

6. **Credibility weights:** Credibility weights were calculated separately by GSC for males and females based on the number of deaths observed in the experience study. Due to the low number of deaths, the weights assigned to the combined group’s experience were low (28% for males and 41% for females). The associated weights assigned to the standard reference table were the compliments of those (72% for males and 59% for females). These weighting factors calculated by GSC used standard actuarial treatment required for developing weighted average mortality that recognizes the credibility level of data in an experience study with insufficient data of its own.

7. **Credibility weighted mortality:** The credibility weights were applied to (a) the experience study mortality rates and (b) standard reference table’s mortality rate (RP2000 as projected to 2012) to obtain the weighted mortality rates. The average rate was 105% of the standard reference table for males and 97% of the standard reference table for females.

8. **Set-forwards and set-backs:** The credibility weighted mortality rates were compared to the standard reference table to set the appropriate set-forwards and set-backs to determine the best fitting table to use for the final mortality assumption. A set-forward of 1 year (in the RP2000 table projected by Scale AA to 2012) was determined by GSC to be the best fit for males and no adjustment to the standard reference table was determined to be the best fit for females.

Therefore, we find the base table (before projection for future mortality) to be fully appropriate for the 2017 Actuarial Valuation.

**Projection scales**

Once the base table was found to be reasonable, we then turned our attention to the projection scale used in the mortality assumption to reflect expected mortality improvements over time. The 2017 Actuarial Valuation stated that the RP2000 table was projected for mortality improvements to 2030. However, the report does not indicate what projection scale was applied. The experience study report did mention the projection Scale AA was used and the 2017 Actuarial Valuation states that the assumptions are based on the results of the experience study. We believe the actuary’s use of Scale AA projected to 2030 is not unreasonable.

However, there is an intermediate projection scale, Scale BB, which was developed to be used in connection with RP2000, pending subsequent creation and release of RP2014 and MP2014. Scale BB was released in September 2012 and available at the time of the experience study. Scale BB was developed after the results of the Society of Actuaries’ analyses showed that the rates of mortality improvement in the U.S. over the then-recent past had differed significantly from those predicted by Scale...
AA. Scale BB would be a better choice for the projection of mortality improvements when coupled with RP2000.

Furthermore, there are two ways to reflect mortality improvement: (a) Project the improvements to a target year in the future or (b) Apply the improvement scale generationally. The first way applies the mortality rate for a 65-year old (for example) regardless of whether the member turns 65 in 2020 or turns 65 in 2040. The generational projection applies the improvements for the years between the observation year and 2020 for a member turning 65 in 2020, but applies the improvements for the years between the observation year and 2040 for a member turning 65 in 2040. While the actuarial literature permits the use of a static projection to a given future year, the actuarial profession is endorsing the generational approach as being preferable.

A more current approach to estimating mortality rates for valuation purposes would be to use either: (a) RP2000 projected generationally by Scale BB or (b) RP2014 loaded with 120% (for CDC data) and adjusted for partially credible plan-specific experience, then projecting generationally using MP2016 or MP2017.

While either of these two approaches would be more current and preferable methodologies, we do not find the mortality tables used in the LARF 2017 actuarial funding valuation report to be unreasonable.
Section 3: Withdrawal Assumption

The 2017 Funding Valuation (page 4) states that “The current year actuarial assumptions utilized for this report are based on the results of an actuarial experience study for the period October 1, 2009 - September 30, 2014, unless otherwise specified in this report.”

We reviewed the experience study report cited above (prepared by GSC, dated January 25, 2016). We also compared the results of the experience study report to the assumptions used in the 2017 Funding Valuation. We note the rates of withdrawal are slightly different. The experience study suggests a withdrawal rate of 10% after one year of completed service down to 2.0% after 10 years of completed service and then back up to 5% for 11 or more years of completed service. The 2017 Funding Valuation shows a withdrawal rate of 10% after one year of completed service down to 0.5% after 10 years of completed service.

Materiality

We do not believe the discrepancy in the withdrawal rates between the experience study report and the actuarial report for funding is a material issue and we have not attempted to determine the impact it would have on the actuarial accrued liability.
Section 4: Gain-sharing Cost-of-living Adjustments

Pages 4-5 of the 2017 Funding Valuation states:

“Although the Board of Trustees has authority to grant ad hoc Cost of Living Increases (COLAs) under limited circumstances, these COLAs have not been shown to have a historical pattern, the amounts of the COLAs have not been relative to a defined cost-of-living or inflation index, and there is no evidence to conclude that COLAs will be granted on a predictable basis in the future. Therefore, for purposes of determining the present value of benefits, these COLAs were deemed not to be substantively automatic and the present value of benefits excludes COLAs not previously granted by the Board of Trustees.”

Certain Louisiana statutes are applicable to all state and statewide retirement systems and provide numerous rules, conditions, thresholds, and benefit levels governing the granting and paying of cost-of-living adjustments or permanent benefit increases. For the purpose of this letter report, we refer to both as COLAs.

For example, R.S. 11:241-248 provides substantive rules applicable broadly to many of Louisiana’s retirement systems, including LARF. These statutes have been in place for a very long time. Certain other Louisiana statutes are applicable to specific retirement systems. For example, R.S. 11:1461 provides substantive COLA rules specifically for LARF.

The broadly applicable rules and the specific system rules have changed over time; significant changes were most recently adopted in 2013 and 2014. Nevertheless, COLA statutes applicable to LARF have been part of the framework for many years. This statutory history of providing a mechanism for LARF’s COLAs continues today.

Currently, the COLA statutes applicable to LARF provide for (a) mathematical and logical rules for when the LARF board may adopt a COLA and (b) mathematical and logical rules for how much COLA the LARF board is permitted to adopt. There is not much if any discretion in the application of these mathematical rules.

When

The statutory mechanism for when the LARF board is allowed to grant base COLAs and additional COLAs depends on the magnitude of a given year’s investment earnings, on whether the funded ratio is at or above certain percentage levels, and on how long it has been since a COLA had previously been granted.

According to page 24 of the 2017 Actuarial Valuation, the funded ratio of LARF was 96.02% as of September 30, 2017. According to the statutes, during the time while LARF’s funded ratio is at least 90% a COLA is allowed every other year subject to the excess earnings rule determining the amount, as described below. However, there may not be complete clarity on exactly how to apply the rules concerning how much time must pass between COLAs.

How much

The statutory mechanism for how much COLA the LARF board may grant (assuming it is permitted to do so based on the conditions above) depends on (a) how far above the threshold the funded ratio is, (b) how
far above the assumed valuation rate the actuarial valuation rate actually was during the year, (c) how much the present value of benefits for eligible members is measured to be, (d) whether it is a base gain-sharing COLA, in which case the increase amount for each eligible member can be up to 3.00%, (e) whether it is an additional gain-sharing COLA, in which case the additional increase amount can be 2.00% of the eligible member’s initial commencement amount, and (f) whether the A+B method in R.S. 11:241 is applied.

**Discretion**

If the conditions outlined in the second step above are satisfied and the LARF board is allowed to grant a base gain-sharing COLA and possibly an additional gain-sharing COLA, the board must vote to actually grant the COLA. The board is free to vote for or against a COLA when allowed, or not to vote at all. This is the discretionary aspect of the gain-sharing COLA-granting process. This discretionary step is what prevents the gain-sharing COLA from being considered “automatic.” But consider the following internal and external forces at play which tend to press board members to grant COLAs when permitted:

a. While we have no personal knowledge of, or experience with, the LARF board, generally speaking, retirement board members often have a sense of duty to serve the plan members. The LARF retirement board of trustees is composed of individuals who have a natural constituency in plan members. There is a natural tendency to recommend COLAs when allowed.

b. Social Security gives a COLA almost every year. In any given future year, if LARF retirees have not had a COLA in a couple years, and since they are not generally covered by Social Security, there is a natural tendency to want to recommend a COLA if allowed.

c. Furthermore, if other retirement systems, such as LASERS, TRSL, or other state or statewide systems, give COLAs in a given year, LARF’s board members will feel pressure to recommend a COLA if allowed.

d. Finally, if the funded ratio of the System continues to improve as it is expected to do, board members might feel like sharing that success with the plan members by recommending a COLA.

On the other hand, the direction of the employer contribution rate (going upward or downward) also influences the willingness to recommend a COLA. Indeed, there are fiscal pressures that move board members at times to refrain from recommending COLAs when permitted if the employer contribution rate goes up by sufficient margins or if the funded ratio falls.

Exhibit 8 on the next page illustrates recent history of when LARF’s COLAs were allowed to be granted and how much. There is history and strong logical support for the presumption that the LARF board will vote for a gain-sharing COLA *whenever permitted* to do so.

- In our opinion, a decision to not measure the likelihoods and magnitudes must be supported by more than an assertion that COLA liabilities do not need to be calculated because COLAs are not automatic.

- Moreover, in our opinion, the lack of any guarantee or certainty about whether the Board will adopt a COLA when permitted to do so is not relevant.

Of far greater importance is the relative magnitude of the liability and its relative effect on contribution requirements.
The likelihood, the *when*, and the *how much* are all actuarially measurable. Based on history and logic, and given the high degree of confidence that the board will grant gain-sharing COLAs whenever permitted, in our opinion, material costs and liabilities of future COLAs should be measured and included in the valuations.

</table>

Given the recent example of granting a COLA when allowed (measured at the fiscal year ending September 30, 2013), coupled with the analysis above, it is our opinion that there is a reasonable likelihood that the board will grant a COLA whenever allowed. It seems unreasonable to “assume” no chance of granting a COLA in future years when otherwise allowed, unless the effect is actuarially determined to be not material.  

**Legislative Framework Presumes COLAs**

The COLA provisions are in the Louisiana statutes for a reason: To pay COLAs – sometimes. The sponsors and other legislators fully presume COLAs to be granted periodically, even if only every few years. If not, these statutory provisions probably would not have been codified.

It is incumbent upon the actuary to recognize the possibility and likelihood that COLA benefits will be paid with some regularity, even if only every few years. That is why we believe the statutory provision is there. Failure to recognize (even if making only a rough estimate) *material* costs and liabilities of the statutes’ COLA provisions is to deny the purpose of the statutes.
**Something is Better Than Nothing**

In the current and prior years, the board’s actuary has posited (a) that one cannot know with any certainty when COLAs will be granted, (b) that no automatically segregated and accumulated (like the state systems) accounts are maintained for the purpose of payment of future cost-of-living increases, and (c) that statutes limit the frequency permitted for granting COLAs. This has been put forth as support for not recognizing future COLAs in advance (the “No Recognition” approach).

Traditional actuarial methods model the payment of various plan benefits over time, none of which are known with certainty. For example: the times when members will terminate, become disabled, die, or retire are not known with certainty; how much employees’ pensionable compensation will increase over time is not known with certainty; nor do we know with certainty what the future investment returns or future inflation will be.

Nevertheless, these uncertainties do not stop us from making reasonable projections using accepted actuarial techniques to measure future costs and liabilities associated with any given plan benefit provision. Decrement events and benefits do not need to be fully predictable before an actuary recognizes their likelihood within an actuarial valuation.

While gain-sharing COLA benefits are different from other benefit provisions in the events and conditions in which the actual benefits arise, they are the same as any other benefit provision in the sense that (a) they are a well-defined benefit payable to plan members, (b) all aspects of their eligibility and calculations can be programmed and calculated using accepted actuarial techniques, and (c) other aspects of their eligibility/approval may be discretionary but do have a reasonably high likelihood of being approved whenever allowed. Actuarially measuring the future costs and liabilities of gain-sharing COLA benefits (recognizing a degree of likelihood and timing) is consistent with our traditional practice of actuarially measuring on a scientific basis other plan benefit provisions (recognizing a degree of likelihood and timing).

Refer to the Appendix A at the end of this letter for several citations from the Actuarial Standards of Practice (ASOPs) pertaining to the valuation of COLAs.

Given the size of LARF’s accrued liabilities and asset portfolio, reasonable scientific actuarial modelling methods are available to the board and its actuary. The modelling methods are affordable and cost-effective: producing information that better identifies the true cost of the LARF benefit program.

Although scientific measurements are superior and preferred, even a rough non-scientific estimate is better than the “No Recognition” approach currently used by LARF. Following the reasoning set forth in the pages above, it is reasonable to expect gain-sharing COLAs to be permitted every other year, in the amount of 2.00% to 5.00% for some or all eligible members each time granted.

**Other Ad Hoc COLAs**

Other plans around the country have no special provisions for COLAs, no well-defined criteria or hurdle to satisfy for granting COLAs, and have no history (or no discernible pattern) of granting ad hoc COLAs. Those are different. In those cases, there is no good reason to expect COLAs to be paid in the future, until or unless some pattern (even if erratic) of truly ad hoc COLAs emerges. But LARF is different, as are other Louisiana retirement systems.

There is a long and specific statutory history with detailed conditions for granting COLAs, fully contemplating that COLAs would be granted. In the past eight years, the only time when a COLA was
allowed to be granted for satisfying the statutory conditions, the board did indeed grant the specified COLA. That, together with other facts presented above, is a strong indicator that there is some likelihood that a COLA will be granted sometimes.

**Reasonable Actuarial Estimates**

There are at least two preferred approaches to actuarially measuring the cost and liabilities of LARF’s COLA provisions. Both scientific actuarial methods involve running actuarial simulations of the future.

1. *Single equivalent annual COLA assumption.* The simulation spins off information about the frequency and magnitude of each year’s permitted gain-sharing COLA. The mean (average) transfer amount can be considered a benefit stream. Solving for X, it determines what would be the single annual equivalent COLA, e.g., 0.35%, or some other such estimated equivalent annual COLA. Solve for the X% that has the same actuarial present value over the next 30 years as the average simulated transfer amount.

2. *Single equivalent benefit load assumption.* Dividing that same mean (average) transfer stream for each year by its regular benefits projected to be payable for that year, as spun off from the open group forecast valuation, provides an estimate of the load on benefits that approximates the average transfer amount, e.g., 4%, 6%, or some other such percent load.

Either of these two alternative *actuarial methods* is acceptable and preferable, in our opinion. Both of these methods are transparent and explicit *actuarial methods* for recognizing the actuarially measurable likelihood of future gain sharing COLAs for funding purposes.

The first method presented above (single equivalent annual COLA assumption) provides a reasonable proxy for what would likely actually happen in the years to come. The value of X% annual COLA serves as the single equivalent COLA, and is treated in the valuation “as if” it is a regular annual COLA increase. The only challenge is to make a reasonable estimate of X% which scientific actuarial methods enable us to do.

**Materiality**

Assuming an actuarial study is prepared that models the future gain-sharing COLAs stochastically, it might turn out not to be material. If it is found not to be material for actuarial funding or for accounting purposes, then the future gain-sharing COLAs would not need to be measured.

Only an actual stochastic model simulating the future gain-sharing COLAs could demonstrate whether the statutory template is expected to produce sufficient future COLAs to be material. Estimating it would likely not be sufficient.

While not a trivial project, the model is fairly easy to build and test, especially if the framework could be used for other statewide systems as well. Refer to the Appendix A at the end of this CAR for a brief summary of the steps typically found in such a project.

**Funding Deposit Account COLAs**

The possibility of COLAs paid from the Funding Deposit Account will disrupt the modelling of the gain-sharing COLAs. This too might render the measurement of gain-sharing COLA liabilities to be immaterial.
Actuarial Certification

This report is considered to be a Statement of Actuarial Opinion. Therefore, I make the following certification:

I, Paul Richmond, am the Manager of Actuarial Services for the Louisiana Legislative Auditor. I am a member of the American Academy of Actuaries, an Associate in the Society of Actuaries, an Enrolled Actuary, and I meet the Qualification Standards of the American Academy of Actuaries necessary to render the actuarial opinions contained herein.

Actuarial Standards of Practice

Cost-of-Living Actuarial Modelling
APPENDIX A

Actuarial Standards of Practice

ASOP No. 4 Section 3.5

3.5 Plan Provisions - When measuring pension obligations and determining periodic costs or actuarially determined contributions, the actuary should reflect all significant plan provisions known to the actuary as appropriate for the purpose of the measurement. However, if in the actuary’s professional judgment, omitting a significant plan provision is appropriate for the purpose of the measurement, the actuary should disclose the omission in accordance with section 4.1(d).

ASOP No. 4 Section 3.5.3

3.5.3 Plan Provisions that are Difficult to Measure - Some plan provisions may create pension obligations that are difficult to appropriately measure using traditional valuation procedures. Examples of such plan provisions include the following:

a. Gain sharing provisions that trigger benefit increases when investment returns are favorable but do not trigger benefit decreases when investment returns are unfavorable;

b. Floor-offset provisions that provide a minimum defined benefit in the event a participant’s account balance in a separate plan falls below some threshold;

c. Benefit provisions that are tied to an external index, but subject to a floor or ceiling, such as certain cost-of-living adjustment provisions and cash balance crediting provisions; and

d. Benefit provisions that may be triggered by an event such as a plant shutdown or a change in control of the plan sponsor.

For such plan provisions, the actuary should consider using alternative valuation procedures, such as stochastic modeling, option-pricing techniques, or deterministic procedures in conjunction with assumptions that are adjusted to reflect the impact of variations in experience from year to year. When selecting alternative valuation procedures for such plan provisions, the actuary should use professional judgment based on the purpose of the measurement and other relevant factors.

The actuary should disclose the approach taken with any plan provisions of the type described in this section, in accordance with section 4.1(i).

ASOP No. 27 Section 3.11.2

3.11.2 Cost-of-Living Adjustments—Plan benefits or limits affecting plan benefits (including the Internal Revenue Code (IRC) section 401(a)(17) compensation limit and section 415(b) maximum annuity) may be automatically adjusted for inflation or assumed to be adjusted for inflation in some manner (for example, through regular plan amendments). However, for some purposes (such as qualified pension plan funding valuations), the actuary may be precluded by applicable laws or regulations from anticipating future plan amendments or future cost-of-living adjustments in certain IRC limits.
Cost-of-Living Actuarial Modelling

Following is a simplified step-by-step explanation of the actuarial simulation process.

An open group forecast valuation of the system forms the basis for a stochastic estimation of the current present values of future COLA benefits. There are other benefits to an open group forecast that prove useful to both actuary and board members as they manage the funding of the system. Once the process solves for X%, the usual closed group valuation is then performed using the X% as a regular COLA.

An Excel spreadsheet can be developed with the necessary open group liability projections, projected fund values based on an investment return for each future year, and annual valuation calculations (annual gain/loss calculation, amortization bases and payments, administrative expense load, experience account balance maintenance, etc.) built into the spreadsheet. With the same expected return every year, the spreadsheet produces deterministic forecast valuations. But if Excel’s random number generator selects return assumptions in a macro from its internal lognormal distribution function, the Fund’s return varies from year to year, producing a stochastic forecast of future valuations.

Running that forecast valuation with and without COLAs, the single equivalent X% can be solved so as to approximate the present value of simulated COLAs.

This is not too complicated for an actuary to design, program, and run. It is being done more and more in many firms across the country. Furthermore, the cost should not be considered too much for a plan the size of LARF (approximately $380 million in assets) for the worthy benefit of obtaining a decent actuarial measure of the cost and liability for providing these COLA benefits. Furthermore, once it is built, it can be adjusted for use on behalf of other retirement systems, thereby spreading the costs.

However, even a rough estimate, not based on scientific or actuarial processes would be better than the “No Recognition” approach used by LARF. Just following the reasoning set forth in the pages above, it is reasonable to expect COLAs to be allowed every other year in the foreseeable future, in the amount of 2.0% to 5.0% for some members each time granted.

Much of the description of the COLA conditions and benefits above are merely a summary and much involves interpretation of statutes. This Comprehensive Actuarial Review should not be considered a legal opinion. The statutes should be consulted for more detailed descriptions and we defer to legal counsel and other authoritative sources for legal interpretations.

Re: Comprehensive Actuarial Review of the 2017 Actuarial Valuation

Dear Kathy:

Attached is our response to the issues discussed in the Louisiana Legislative Auditor’s Comprehensive Actuarial Review of the 2017 Actuarial Valuation.

If you have any questions, please give me a call.

Sincerely,

[Signature]

Gregory M. Curran, FCA, MAAA, ASA, EA  
Consulting Actuary
The following represents G. S. Curran & Company’s written response to the Comprehensive Actuarial Review (CAR) of the 2017 Louisiana Assessors’ Retirement Fund (LARF) Actuarial Valuation prepared by the Louisiana Legislative Auditor (LLA).

“Overly Optimistic Return Assumption”

The Comprehensive Actuarial Review of the 2017 Actuarial Valuation expresses a significant difference in opinion between the actuaries employed by the LLA and G. S. Curran & Company with regard to the valuation interest rate (or investment return assumption). This significant difference stems from a few separate items: a lower net inflation assumption, the use of 10 year expected rates of return to develop the return assumption, and a tendency to develop a single point estimate return assumption as opposed to determining a reasonable range for return assumptions.

The LLA discusses the need for a disciplined process to setting the return assumption. It is my belief that the LLA is well aware that G. S. Curran & Company does use a disciplined process of collecting and analyzing information from many expert investment consultants and forecasters. The expert information utilized includes expected real rates of return for each available asset class, standard deviations of returns for each available asset class, and the correlations between asset classes. G. S. Curran & Company has consistently used such expert information to determine a reasonable range of assumed rates of return based directly on the system’s target asset allocation and to provide advice to the Board of Trustees. As asset allocations have changed and as expert opinions have changed, G. S. Curran & Company has provided revised recommendations to the Board of Trustees. In response, the Board of Trustees has reduced the assumed rate of return multiple times in the past decade based on our recommendations.

Our review process consists of the following:

To set the expected nominal rate of return, we first project the expected real rate of return determined based on the target asset allocation set by the Board. One significant difference in our approach is the use of 20-30 year projections instead of 10 year projections for setting these economic assumptions. We simply do not agree with the LLA with regard to the appropriate time horizon to consider in setting either the assumed rate of return or inflation rate. It is our belief that although the use of 10 year projections today are conservative versus 20-30 year projections, this has not and will not always be true.

We believe that conservatism in the assumed rate of return assumption is appropriate, but despite the fact that a 10 year projection basis is conservative in 2018, if the systems consistently set their assumed rate of return based on 10 year forward projections of investment returns, this assumption is likely to fluctuate greatly and will in some periods reach levels in excess of a reasonable range set based on 20-30 year projections. Shorter term assumptions are significantly more volatile than longer term assumptions since recent investment return experience and market conditions more heavily influence shorter term measures. For instance, 10 year investment projections today are heavily influenced by expectations related to near term inflation, recent stock market experience, and projections related to the expected direction of interest rates. Longer term expectations are also impacted, but the expected impacts of recent macro-economic events and current economic cycles are mediated by the use of longer term “normalized” economic measures.
One example of how shorter term assumptions can be heavily affected by current economics is the impact of expected increases in interest rates on fixed income investments. With interest rates at historically low levels and most forecasters expecting rates to rise in the near term, ten year projections of fixed income returns are heavily influenced by the expected impact of rising rates on bond values. But, with rising rates comes higher expected fixed income returns on reinvested capital. By using only a ten year projection period, the LLA sets discount rates using projections heavily influenced by the effect of rising rates on fixed income values without capturing the bulk of higher returns due to reinvesting capital at higher rates in the future.

We have reviewed the inflation expectations of many experts and have used that information to develop our reasonable range for the long-term inflation assumption. Our ongoing review of this long-term inflation assumption has led us to reduce the assumption as economists and forecasters have brought their expectations lower, but we find reason to be concerned that inflation forecasting has often been influenced by static analysis with regard to tax policy and future economic growth. A survey of economists finds sharp disagreement as to the potential impact of the structural changes recently made to the U.S. tax code. Recent growth in GDP has coincided with increases in inflation rates. This is not sufficient to prove that future long-term inflation will be higher, but it does point out that despite the efforts of government to set an inflation target, actual inflation reacts to macroeconomic conditions.

As we have pointed out over the last nine months, the implications of structural changes to the U.S. tax code are uncertain, but such changes could spark spending and lead to increased GDP growth. In fact, GDP growth has increased since the passage of changes in the tax code. Business leaders like the J.P. Morgan chief U.S. economist suggested that the tax bill was supportive of inflation and further Federal Reserve rate hikes. Due to the politics of tax law changes, forecasts are often clouded by political ideology. This is evident in the vastly differing opinions of economic impact estimates of the tax changes produced by economists.

In 2017 we provided evidence related to our projections of long-term inflation rates to the Legislative Auditor. This was prior to the passage of significant changes in the tax rates. We believe that it will take time for these changes to be contained within published forecasts by the Federal Reserve and Social Security Administration. Further, when we review the vast set of expert opinions related to expected long-term future inflation, what is most evident is the degree of uncertainty. This is demonstrated by the remarks of Federal Reserve Chair Janet Yellen on September 26, 2017 at the 59th Annual Meeting of the National Association for Business Economics. In her remarks, the former Fed Chair discussed inflation expectations and the many inputs to be considered. Although her remarks did not settle the issue related to expected inflation, they did clearly show that the Federal Reserve recognized how difficult it is to predict inflation. Within her remarks are suggestions that inflation may remain low, but she includes statements like, “Key among current uncertainties are the forces driving inflation, which has remained low in recent years despite substantial improvement in labor market conditions.” Also, she states, “Some of the recent decline in inflation, although not all, reflects idiosyncratic shifts in the prices of some items, such as the large decline in telecommunication service prices seen earlier in the year, that are unlikely to be repeated.” Ms. Yellen added, “Although we judge that inflation will most likely stabilize around 2 percent over the next few years, the odds that it could turn out to be noticeably different are considerable.”
With this level of uncertainty, which has always existed around such economic assumptions, it has been our policy to slowly move our long-term assumptions in a direction supported by a majority of expert opinions while remaining within what we consider the reasonable range for long-term inflation. Ms. Yellen suggests that the Federal Reserve uses the same method to adjust monetary policy when she says, “How should policy be formulated in the face of such significant uncertainties? In my view, it strengthens the case for a gradual pace of adjustments. Moving too quickly risks overadjusting policy to head off projected developments that may not come to pass.” We believe that the large moves suggested by the LLA could very well be just that, over adjustments.

Therefore, we fully believe that the long-term rate of inflation assumption of 2.50% utilized in our 2017 actuarial valuation is reasonable.

With regard to the return assumption, we believe that our process of reviewing the assumed rate of return based on the system’s particular target asset allocation and a collection of data from many investment consulting firms with regard to long-term expected rates of return, standard deviations of return, and correlations for each asset class is more than defensible. It would appear that the main reason for the difference in our range of reasonable return assumptions with that developed by the Louisiana Legislative Auditor is time frame. We, in keeping with a majority of public plan actuaries, believe that the appropriate return assumption is based on expected rates of return and inflation over the long-term (20 – 30 years). The LLA has suggested that a 10 year assumption is more appropriate. In our opinion, the use of mid-term assumptions will lead to frequent changes in assumptions as markets go up and down and assumptions are adjusted for expected near and mid-term performance. We believe that assumptions based on 10 year time horizons will be more volatile and will tend to build in recent experience so that recent out-performance will tend to result in lower 10 year forecasts. In addition, long-term forecasts are not necessarily less reliable than mid-term assumptions. Although determining a reliable long-term point estimate of future returns is difficult, forecasting over longer periods has the advantage of the averaging process to reduce the volatility of outlier returns.

The LLA’s own Comprehensive Actuarial Review of the Firefighters’ Retirement System in 2017 showed a significantly lower consensus expectation than their review just one year prior. We find the drastic change in the LLA’s own recommendation for the only system tested in both years to be a concerning sign of how volatile mid-term assumptions and simple point estimates can be. A comparison of the two Comprehensive Actuarial Reviews show that the 6.7% consensus expectation stipulated in 2017 was reduced to 6.0% just one year later. Such volatility in recommended discount rates shows how dependent the end result is on the inputs to the process.

The LLA states that the system’s 6.75% rate of return assumption and the 2.5% inflation assumption are not mainstream. We believe that our assumptions for the Assessors’ Retirement Fund are conservative to the consensus mainstream of professional investment forecasters for long-term return and inflation assumptions. Although we do not set our return assumption by looking at the assumptions used to value other public plans, when considering whether our assumption is “mainstream” it can be instructive to compare to other public plans. In this case, the system’s assumed rate of return and inflation assumption are well below the mean and median return assumptions of the nearly 150 public employee retirement systems represented in recent NASRA surveys. It’s simply unreasonable to claim that the Board’s assumed rate of return and inflation rate are outside the consensus mainstream.
The most recent reduction from 7% to 6.75% as of September 30, 2017 was not made based on a determination that the 7% assumption was not within the reasonable range, but rather a desire for greater conservatism within the plan’s assumptions due to the lower risk appetite of the Board of Trustees, to account for the small size of the fund and the investment limitations that the size puts on the fund, and as a method of protecting the current high funded ratio.

**The Mortality Assumption**

G. S. Curran & Company provided detailed information with regard to the method of setting mortality assumptions and since the LLA found the tables in use to be reasonable, we have not provided further discussion. We will, of course, continue to review the plan’s mortality assumption as part of the experience study process. Changes to account for updated information related to mortality experience of the plan, mortality improvement scales, and even the use of static vs. generational mortality will be considered within each future experience study.

**Withdrawal Assumption.**

The LLA states in the CAR that “The rates of withdrawal are slightly different than disclosed in the experience study. However, we do not believe the discrepancy is a material issue and we have not attempted to determine the impact it would have on the actuarial accrued liability.”

A review of the Experience Study and the 2017 Actuarial Valuation Report finds that the values shown in the valuation report properly reflect the results of the study performed, but that the labeling in the Experience Study was not accurate. The first value applies to members with less than one full year of service credit, not those who have completed a full year. Therefore, the 0.005 factors apply to those with at least 9 years (not at least 10 years) of service credit.

**The handling of Cost-of-Living Adjustments within the funding valuation report**

In the CAR, the LLA states, “Currently, the COLA statutes applicable to LARF provide for (a) mathematical and logical rules for when the LARF board may adopt a COLA and (b) mathematical and logical rules for how much COLA the LARF board is permitted to adopt. There is not much if any discretion in the application of these mathematical rules.” We would point out that the statutes do provide definite formulas or mathematical rules for the maximum amount of any COLA allowed to be offered. They further stipulate ASS conditions under which the Board may elect to grant a COLA.

R. S. 11:1461(A) states that “The board of trustees may use excess interest earnings on investments of the system in excess of normal requirements as determined by the actuary to provide a cost-of-living increase …” This may seem to imply that COLA costs are paid out of excess interest earnings, but with no segregation of investment earnings into a gain sharing account, mathematically the cost impact of a COLA is to either increase the present value of future benefits and therefore the required employer contributions of the system. In fact, by accumulating excess contributions prior to granting COLAs, the Funding Deposit Account mechanism allows the Board to truly prefund COLAs. It has been partly with this in mind that the LARF Board of Trustees
has continued to accumulate funds in the Funding Deposit Account by requiring employers to pay higher employer contribution rates than the minimum set by PRSAC. The Board has done so consistently since 2006 with three additional decisions to hold rates above the minimum prior to that year. From those actions, as of September 30, 2017 the Funding Deposit Account Balance was $34,439,283. This balance is equal to more than 16 times the present value of the most recent Cost of Living granted.

Although we recognize that formulas exist within the statutes that limit the payment of COLAs and set the maximum formula for the amount of COLA available when legislatively authorized, there is no automatic feature related to COLAs in the statutes and no portion of investment gains are automatically segregated for the purpose of the payment of future cost of living increases. This construct does not act as a guarantee that a portion of gains will be used to pay COLAs. Therefore, we disagree with the LLA’s characterization of the applicable COLA provisions as gain-sharing.

To the extent that the Board is allowed by statute to offer COLAs in the future, it is our expectation based on conversations with the Board and based on the significant balance in the Funding Deposit Account, that such COLAs will not affect the net liabilities of the fund. By releasing additional assets from the Funding Deposit Account equal to the expected increase in the present value of future benefits related to the COLA, employer costs will not be materially affected by such Board decisions.

Based on our expectations and discussions with the Board related to future plans to use the Funding Deposit Account to fund COLAs, we believe that it would be inappropriate to increase liabilities within the funding valuation to account for future COLAs.
